Adding a subdomain

Hosting panel · https://kyzoe.be/en/docs/adding-a-subdomain/

Our **kyzoe.be hosting packages** are designed for a single application, such as WordPress. However, if you want to add an extra subdomain with a simple HTML or PHP website, you can easily do so by following the guide below.

If you need hosting for several applications, we recommend purchasing an additional hosting package.

Adding a subdomain in the Kyzoe client area

1. Log in to your **cp.kyzoe.be** account.
2. In the left-hand menu, click **Websites** and select the website to which you want to add an extra domain.
3. In the top menu, click **Domains** and then **Add domain**.
4. You will now see three options: **Addon**, **Subdomain** and **Alias**.
   In this guide we use the **Subdomain** option.
5. Enter the subdomain you want, without the `www.` part.
6. Under **Document root** you can set a custom folder if you want to use separate content for each subdomain.
   We recommend using the name of the subdomain here, without the domain extension (for example: `jouwsubdomein`).
7. The subdomain has now been added, but the corresponding folder still has to be created manually.
   Via the top menu, go to **Files**, click **New** → **Folder** and give the folder the same name as the chosen document root (for example `jouwsubdomein`).
8. Click **Create**.

You can now upload your website files to this folder. Once everything is ready, you can change the domain’s nameservers to put the subdomain live.
